

Brainstorming – Idea Generation

Understanding the Need

Every organization depends on a stable and secure network infrastructure for its daily operations. Employees frequently raise requests for services such as **new network connections, office relocations, device configuration, internet access, and network support**. In many workplaces, these requests are still handled through emails, phone calls, or verbal communication. This often leads to delays, incomplete information, duplicate requests, and difficulty in tracking the request status.

Idea Generation Process

The main idea behind this project was to design a **simple, structured, and automated request management system** using ServiceNow.

During brainstorming, the following questions were considered:

- How can users submit network requests without sending emails?
- How can all request information be collected in a single form?
- How can the request process become faster and more transparent?
- How can manual work for the Network Team be reduced?
- How can every request be tracked from submission to completion?

These questions helped shape the final solution.

Proposed Idea

The solution is to create a **Network Request Management** application using the **ServiceNow Service Catalog**. The application provides a user-friendly request form where employees can submit all required network-related requests. The system captures requester information, request details, and device information in a standardized format, making the entire process organized and easy to manage.

Expected Outcome

The proposed solution aims to:

- Simplify network request submission.
- Eliminate manual request handling.
- Improve request accuracy.

- Reduce response time.
- Increase transparency through request tracking.
- Enhance communication between users and the Network Support Team.
- Build a scalable foundation for future workflow automation.
