

Final Project Report

Automated Network Request Management using ServiceNow

1. Introduction

The **Automated Network Request Management** project is developed using the ServiceNow platform to simplify and automate the process of handling network service requests. Users can submit requests through the Service Catalog, and the system automatically creates a record in the custom **Network Database** table, sends a confirmation email, and initiates the approval workflow. This reduces manual effort and improves request management.

2. Project Objective

The objective of this project is to automate the network request handling process by:

- Providing an easy-to-use Service Catalog form.
- Automatically creating request records.
- Sending email notifications.
- Managing approval workflows.
- Storing all request details in a custom database table.

3. Problem Statement

Traditional network request handling involves manual emails and paperwork, making it difficult to track requests and causing delays. This project provides an automated solution to efficiently manage network requests within ServiceNow.

4. Project Modules

Module 1 – Network Database Table

A custom table named **Network Database** was created to store network request details such as request number, customer information, device details, address, assignment group, and work status.

Module 2 – Service Catalog

A custom catalog item was created to allow users to submit network requests through the Service Portal.

Module 3 – Request Information

The request form collects:

- Requested For
- Customer Information

- Device Details
- Customer Address
- Network Service Requirements

Module 4 – Flow Designer

An automated workflow was created to:

- Retrieve catalog variables.
- Create a record in the Network Database table.
- Send a confirmation email.
- Trigger the approval process.

Module 5 – Email Notification

After a request is created, an email notification is automatically sent to the requester confirming successful submission.

Module 6 – Approval Workflow

The request is routed through the approval process before further processing.

5. Workflow

1. User opens the Service Portal.
2. User selects the **Network Request** catalog item.
3. User fills in the request form.
4. User submits the request.
5. Flow Designer starts automatically.
6. A record is created in the **Network Database** table.
7. A confirmation email is sent to the requester.
8. The approval workflow is initiated.
9. The request is stored for tracking and future processing.

6. Technologies Used

- ServiceNow
- Service Catalog
- Flow Designer
- Custom Tables

- Catalog Variables
- Email Notifications
- Approval Workflow

7. Key Features

- Automated network request creation.
- Custom Network Database table.
- User-friendly Service Catalog form.
- Flow Designer automation.
- Automatic email notifications.
- Approval workflow.
- Centralized request tracking.

8. Advantages

- Reduces manual work.
- Improves request tracking.
- Faster request processing.
- Automatic email communication.
- Organized data storage.
- Better user experience.

9. Project Output

The project successfully automates the complete network request lifecycle. When a user submits a request through the Service Portal, the system automatically creates a request record, stores it in the **Network Database** table, sends a confirmation email, and initiates the approval process. This ensures efficient request handling with minimal manual intervention.

10. Conclusion

The **Automated Network Request Management** project demonstrates the effective use of ServiceNow to automate IT service management processes. By integrating the Service Catalog, Flow Designer, custom tables, email notifications, and approval workflows, the project delivers a reliable, scalable, and user-friendly solution for managing network service requests efficiently.
